

4 Months: Recognizing Early Motor Delays

A Comparison Examination of 4 Month Old Infants

Typical

Atypical

Exhibits midline and symmetry of head, eyes, arms and legs Shows visual engagement

- Shows visual engagement and reaches out against gravity
- Demonstrates frequent antigravity extremity movement, dissociating from a more stable trunk

- Displays asymmetry of head and extremities, with head tilted and body curved
- Does not show a balance between extension and flexion
- Moves extremities randomly, but without expected antigravity movement
- Is not visually engaged and does not track object

idelying

- Uses upper arm and dissociated lower extremities to assist in facilitated roll
- Sustains sidelying posture with a balance of trunk flexor and extensor muscles
- Lifts head and upper trunk off the surface in preparation for independent rolling

- Exhibits sluggishness in top arm during facilitated roll
- Does not sustain sidelying posture; has inadequate control in position
- Cannot lift head and upper trunk off support surface

Prone

- Brings shoulders and upper arms forward with elbows in front of shoulders
- Shows progression toward lower extremity extension and adduction
- Moves arms forward to reach for an object; turns head freely to follow object
- Displays extensor activity into the lumbar spine

- Has flexed hips which shifts weight forward while keeping elbows behind shoulders
- Uses only neck extension instead of forearm weight bearing; head lifting is unsustained
- Does not have the capability to shift weight onto lower extremities

ill To Sit

- Maintains head in midline without head-lag and with good chin tuck
- Lifts legs and activates trunk muscles to assist in maneuver
- Pulls forward with both arms and abdominals to assist further in pull to sit

- Demonstrates head-lag and cannot sustain head lifting once upright
- Does not pull with arms; no upper extremity participation
- Appears not to anticipate movement toward sitting

4 Months: Recognizing Early Motor Delays

A Comparison Examination of 4 Month Old Infants

Typical

- Does not sustain head lifting; cannot turn head to look sideto-side
- Must be held high under the armpits for support
- Uses extremity posturing to compensate for decreased proximal strength

Atypical

Horizontal Suspension

 Able to keep neck and trunk extended with head upright to 45 degrees, steady and in midline

 Shows good head control and chin tuck, with head in

Requires support only

at hips and pelvis; has

extension to mid-thoracic

· Begins to move in anterior-

posterior planes and comes

back from forward flexion at the hips into upright sitting

midline

spine

- Shows trunk extension into lumbar spine and scapular adduction
- Freely moves arms and legs

- Able to hold head up briefly but cannot maintain it in midline
- Cannot sustain thoracic trunk extension and does not show hip extension
- Cannot maintain trunk extension while moving arms and legs

Protective Extension

- Displays extension through neck, trunk and hips that is maintained during forward tilting
- Cannot bring arms fully forward to surface because they are being used to sustain extension

- Unable to sustain strong neck, trunk and hip extension during forward tilting
- Uses excessive asymmetry and flexed arms to sustain extension to avoid hitting his head

tanding

- Keeps hips just behind shoulders
- Has active extension into lower thoracic and lumbar spine, but no full hip extension
- Can sustain standing posture; requires minimal support at lower trunk to aid in balance

- Requires support in the upper thoracic area to sustain standing
- Intermittent extension used to produce head lifting
- Shoulders remain well forward of hips
- Lacks adequate hip and trunk control for sustained weight bearing
